A fixed-window probability can hide different demand timing
(a) Constructed cumulative distributions
Cumulative demand probability $F_U(r)$
Prefix A
Prefix B
Both: $F_U(3\,\mathrm{s}) = 0.2$
Remaining time (s)
(b) Finite-horizon score: $H = 30$ s, $\tau = 10$ s
Total score: A = 0.402 B = 0.211
Discounted mass $e^{-r/\tau}\,\Delta F_U(r)$
0.181
0.181
0.221
0.000
0.000
0.030
Interval right endpoint (s)
Constructed illustration, not measured data.
Both examples assign 0.8 probability to demand by 30 s; the remaining 0.2 has no assumed outcome.
